

Firewall Access Layer Switch

Overview

Access, Distribution, and Core Layers Explained Switches in this layer are called access switches. End devices connect to the LAN through Choose access laye.

Key Takeaways

A Firewall Access Layer Switch connects end devices to the network while enforcing security policies through VLANs and firewall integration. Role of Access Layer Switches

Access layer switches serve as the entry point for endpoints such as computers, IP phones, printers, IoT devices, and wireless access points. They provide high port density, PoE support, and VLAN segmentation to ensure secure and efficient connectivity for all devices on a floor or subnet . These switches typically connect upstream to distribution or aggregation switches, which then link to the core network .

Integration with Firewalls

Firewalls are often deployed at the edge of the access layer or between the access and distribution layers to enforce security policies, control traffic, and segment networks. In practice, firewall ports are connected to access switches to manage traffic for specific VLANs, such as LAN, DMZ, or WANHA networks . This setup allows the firewall to inspect traffic from multiple endpoints while the access switch handles local switching.

VLAN and Port Configuration

- **VLAN Segmentation:** Access switches use VLANs to separate traffic types (e.g., user devices, servers, DMZ). Each VLAN is assigned to specific ports on the switch .
- **Port Assignment:** Ports connected to firewalls are often tagged for multiple VLANs or untagged for a single VLAN, depending on the network design .
- **Ingress Filtering:** Enables the switch to enforce which VLANs or traffic types are allowed on each port, enhancing security .

Redundancy and High Availability

To ensure resiliency, access switches can be connected in redundant pairs with multiple uplinks to aggregation switches. Firewalls may also be deployed in HA pairs, with dedicated links to access switches for failover . This ensures continuous connectivity even if a switch or firewall fails.

Best Practices

- Use Layer 2+ or Layer 3 switches depending on whether routing is required at the access layer .
- Ensure sufficient port density and bandwidth to support all endpoints and PoE devices .
- Implement VLANs and ACLs to segment traffic and enforce security policies.
- Connect firewalls to access switches using tagged VLANs for DMZ, WAN, and internal networks.
- Plan for redundant uplinks and HA firewalls to maintain network availability . By combining access layer switches with firewalls, organizations can achieve secure, scalable, and manageable network access for all endpoints while maintaining centralized control over traffic and security policies.
