

How to identify the model number of a surveillance optical module

Overview

How to identify optical module model Check the Module Label Most optical modules have a label that includes manufacturer, production date, module type, tran.

Key Takeaways

The model number of a surveillance optical module can be identified through physical labels, manufacturer datasheets, EEPROM data, or network device commands. Physical Inspection

Most optical modules, including SFP, SFP+, XFP, QSFP, and CFP types, have a label on the module housing that lists the model number, vendor, serial number, and other key specifications. For example, SFP modules often display the data rate (e.g., 1G, 10G), fiber type (single-mode or multimode), and reach (SR, LR, ER). Carefully inspecting this label is the simplest method to identify the module without removing it from the network device.

Using Device Commands

For modules installed in network equipment, you can retrieve model information via software commands:

- Cisco devices: Use commands like show inventory, show interface transceiver detail, or show logging | include transceiver to display the Product ID (PID), Version ID (VID), serial number, and Digital Diagnostic Monitoring (DDM) metrics such as temperature, voltage, and optical power.

- Linux-based systems: Tools like ethtool can query SFP modules connected to NICs, providing vendor, model, part number, transceiver type, cable length, and connector type . These methods allow you to identify the module without physically removing it, which is useful for live systems.

Interpreting Model Numbers

Optical module model numbers are typically alphanumeric codes that encode manufacturer, product series, data rate, laser type, and other specifications :

- Prefix letters often indicate the manufacturer or product series (e.g., GLC for Cisco Gigabit Link Card).
- Numbers usually represent the supported data rate (e.g., 10G for 10 Gigabit).
- Suffix letters may indicate fiber type, reach, or special features (e.g., LR for long reach, SR for short reach, MMD for multimode diagnostic). By consulting the manufacturer's datasheet or official compatibility matrix, you can decode these codes to confirm the module's specifications and ensure compatibility with your equipment.

EEPROM and Diagnostic Data

Many modern optical modules include EEPROM memory that stores detailed information about the module, including model number, serial number, and operational parameters. Reading this data via network commands or diagnostic software provides a reliable method to identify the module and monitor its health.

Summary

To identify a surveillance optical module's model number:

- Check the physical label on the module for printed model and vendor information.
- Use network device commands (e.g., show inventory, ethtool) to retrieve module details remotely.
- Decode the alphanumeric model number using manufacturer documentation to understand data rate, fiber type, and reach.
- Access EEPROM or DDM data for precise identification and operational metrics.

Mastering these methods ensures accurate identification, supports maintenance, and prevents compatibility issues in high-speed optical networks .
