

Linked optical module

Overview

An optical module is a typically hot-pluggable optical transceiver used in high-bandwidth data communications applications. Optical modules typically have an electrical interface on the side that connects to the inside of the system and an optical interface on the side that connects to the outside world through a fiber optic cable. The form factor and electrical interface are often specified by an interested group using a multi-source agreement (MSA).

Key Takeaways

A linked optical module, or optical link module, is a compact device that converts electrical signals into optical signals for high-speed data transmission over fiber optic cables.

Overview

A linked optical module, also known as an optical transceiver, serves as the physical bridge between electronic devices and fiber optic networks, enabling data transfer at speeds up to 800 Gbps . It operates at the physical layer of the OSI model, performing photoelectric conversion: electrical signals are converted to light for transmission, and incoming light signals are converted back to electrical signals for processing .

Composition and Working Principle

Optical link modules typically consist of:

- Transmitter (TOSA): Contains a laser diode or LED that emits modulated light signals driven by a driver chip.

- Receiver (ROSA): Contains a photodetector that converts incoming optical signals into electrical signals, often amplified by a preamplifier.
- Functional circuits and interfaces: Manage signal processing, biasing, and communication with the host system . The module connects electrically to the host system and optically to fiber cables, often in a hot-pluggable form factor such as SFP, QSFP, CFP, or XFP .

Types and Form Factors

Optical modules come in various types depending on speed, distance, and application:

- SFP/SFP+: Small form-factor pluggable modules for 1-25 Gbps.
- QSFP/QSFP28: Quad small form-factor modules for 40-100 Gbps.
- CFP/XFP: Larger modules for 100-400 Gbps.
- Emerging architectures: LPO (Linear-drive Pluggable Optics), NPO (Near Package Optics), and CPO (Co-Packaged Optics) improve bandwidth density, reduce latency, and enhance energy efficiency for AI and HPC systems .

Applications

Linked optical modules are widely used in:

- Data centers and high-performance computing: For high-speed interconnects between servers, switches, and storage.
- Telecommunications: Enabling long-distance fiber optic communication.
- Industrial networks: Such as PROFIBUS systems, where optical link modules ensure reliable and safe data transmission .

Key Considerations

When selecting an optical module, consider:

- Data rate and distance: Ensure the module supports the required bandwidth and transmission length.
- Form factor compatibility: Match the module to the host system's interface.
- Power consumption and thermal management: Critical for high-speed modules to maintain performance and reliability .
- Ecosystem compatibility: Emerging LPO and NPO modules may require single-vendor environments due to early standardization stages . Linked optical modules are essential components in modern high-speed networks, bridging electronic systems with optical fiber infrastructure while supporting scalable, low-latency, and energy-efficient communication.
